NOTES

- B. Caution to Electronic Equipment Design Engineers: Special attention should be given to the working temperature of a valve operating in an airborne equipment. Reliability will be seriously impaired if the maximum bulb temperature is exceeded. The life expectancy may be reduced if conditions other than those specified for Life Test are imposed on the valve and will be reduced appreciably if absolute maximum ratings are exceeded. Both reliability and performance will be jeopardised if the heater voltage rating is exceeded; life and performance reliability are directly related to the degree that the regulation of the heater voltage is maintained at its centre-rated value.
- C. Two valves operating in a full-wave circuit. Input Voltage = 500 0 500V rms.
- D. Two valves operating in a full-wave circuit. Input Voltage = 625 0 625V rms.

TESTS

To be performed in addition to those applicable in K1001 Tests shall be performed in the specified order unless otherwise agreed with the Inspecting Authority

NOTES

- 1. Measured in a 50 c/s half-wave circuit, Initially, the total supply impedance (including transformer) shall be adjusted, so that a valve giving an output current of 150 mA DC for a voltage drop across the valve of 227 DC, will give an output current of 125 mA with an anode load resistance of 5k and a reservoir condenser of 8 µF. The heater-cathode voltage shall be the output voltage. The anode voltage shall be measured directly from anode to earth using a normal rectifier meter.
- 2. The valve shall be cold when inserted into the test socket. Alternatively, it may be inserted into a preheating panel and operated under conditions similar to those obtaining in Note 1, with the output voltage appearing between heater and cathode. Valves shall be rejected which spark, flash more than once, or show heater-cathode breakdown initially or when fully heated.
- 3. Arcing within the valve shall be cause for rejection when the anode voltage is switched on and off six times. This test may be combined with the voltage breakdown test in Group A.
- 4. As for Note 1, except that the output current shall be 150 mA with a load resistor of 3k.
- 5. The Life test circuit shall be adjusted so that, using a load resistor of 3k (approx) and a reservoir capacitor of 8 m² (approx), an output current of 150 mA is obtained with a peak current greater than 900 mA but not more than 1A.
- 6. Measured with cathode positive with respect to heater and with a series resistor of 330k.
- 7. As for Mote 1, but with the reservoir condenser adjusted to suit the test frequency. Test at any convenient frequency within the range 1.5 to 2.4 kc/s.

ELECTRONIC VALVE SPECIFICATION

SFECIFICATION MOS/CV4036 ISSUE 2 DATED 6th NOVEMBER, 1956

AMENDMENT No. 1

Page 3 GROUP E Life Test

In Test Conditions Column, Line 2:-

Amend Vhk = V out + 350 V rms to read Vhk = V out + 150 V rms

27th October, 1958.

 $T_{\bullet}V_{\bullet}C_{\bullet}$ for $R_{\bullet}R_{\bullet}E_{\bullet}$
